US93 N, Flathead Indian Reservation, Montana (2002-2015)

- “Road is a visitor”
- Respectful to land
- “Spirit of the place”
- Cultural values
- Natural resources
Main Questions

• Human safety: Wildlife-vehicle collisions
• Habitat connectivity: Wildlife use crossing structures
• Cost-benefit analyses

• Contract research
• WTI-MSU and CSKT
• Students and other partners at MSU and UofM
2 Projects, 1 Purpose

“Before”
2002-2007
Data 2002-2005

“After”
Data 2002-2015
Fences
8.71 miles (14.01 km) both sides

Crossing structures
39 locations for mammals
Fences

Functions:
1. Keep wildlife from accessing the highway
2. Help guide wildlife towards the safe crossing opportunities
Crossing Structure Types

Functions
1. Allow wildlife to safely cross the highway
2. Reduce wildlife intrusions into fenced road corridor

1 Overpass
2 Over span bridge
3 Large underpass
4 Box culvert
5 Small culvert
Carcasses 2002-2015

- White-tailed deer (*Odocoileus virginianus*), 881, 96%
- Mule deer (*Odocoileus hemionus*), 25, 3%
- Deer (*Odocoileus spec.*), 2, 0%
- Black bear (*Ursus americanus*), 12, 1%
- Grizzly bear (*Ursus arctos*), 1, 0%
- Elk (*Cervus canadensis*), 2, 0%
Wildlife-Vehicle Collisions

- Evaro-Polson (excl. Ninepipe area)
- Only 16.8% with fences!
Deer Pellet Groups

Evaro

Ravalli Curves, Ravalli Hill

Deer population similar before-after
BACI Study Design

- 3 “long” fenced sections
- Before-After
- Control-Impact
Effectiveness Fences

Effect of the highway reconstruction (before-after) on the number of carcasses/crashes depended on the treatment (wildlife fences and wildlife crossing structures vs. no fences)

**Carcass data:** -71%

**Wildlife-crash data:** -80%

*Interaction P=0.036*

*Interaction P=0.026*
Situation

Trend to implement
• Crossing structures with limited wildlife fencing
• Crossing structures without wildlife fencing

Especially in multifunctional landscapes
Reducing Wildlife-Vehicle Collisions

< 5 km: 52.7% range 0-94%
> 5 km: typically > 80%
Reducing Wildlife-Vehicle Collisions

Why lower?

<5 km: under partial or full influence of fence end effects
Reducing Wildlife-Vehicle Collisions

Fence end effect is indeed present
Reducing Wildlife-Vehicle Collisions

Why more variable?

Local situation fence ends
always different

Short fences (<5 km):
Fence end effect immediately noticeable in overall effectiveness

Long fences (>5km):
Fence end effect diluted
Safe Crossing Opportunities for Wildlife

- Highly variable
- Short fences: can have high use
- Long fences: can have low use

Local situation very important
- Wildlife presence
- Habitat guides them to structure
- Factors that keep them away?

Bear-vehicle collisions 2002-2015

Black bears

Grizzly bears
Bear-vehicle collisions

Interaction $P = 0.320$

No reduction in the three main fenced areas

Why?
Large mesh sizes
Wooded posts
No overhang
Gaps in fence
Conclusions

- 70-80% reduction wildlife-vehicle collisions in three main mitigated areas
- Increase in collisions in unmitigated sections
- Road length fences ≤5 km: Lower effectiveness, more variable
- No reduction in black bear mortality
- Grizzly bears continue to be hit
29 Structures, 5 years

- 95,274 successful crossings
- 22,648 per year
- 20 wild medium-large mammal species
  - 1,531 black bear
  - 958 coyote
  - 568 bobcat
  - 227 mountain lion
  - 29 grizzly bear
  - 38 badger
  - 32 elk
  - 14 beaver
  - 13 otter
  - 3 moose

**Cost–Benefit Analyses of Mitigation Measures Aimed at Reducing Collisions with Large Ungulates in the United States and Canada: a Decision Support Tool**

Marcel P. Huijser1, John W. Duffield2, Anthony P. Clevenger3, Robert J. Ament4, and Pat I. McGown5

ABSTRACT. Wildlife–vehicle collisions, especially with deer (Odocoileus spp.), elk (Cervus elaphus), and moose (Alces alces) are numerous and have shown an increasing trend over the last several decades in the United States and Canada. We calculated the costs associated with the average deer-, elk-, and moose–vehicle collision, including vehicle repair costs, human injuries and fatalities, towing, accident attendance and investigation, monetary value to hunters of the animal killed in the collision, and cost of disposal of the animal carcass. In addition, we reviewed the effectiveness and costs of 13 mitigation measures considered effective in reducing collisions with large ungulates. We conducted cost–benefit analyses over a 75-year period using discount rates of 1%, 3%, and 5% to identify the threshold values (in 2007 US dollars) above which individual mitigation measures start generating benefits in excess of costs. These threshold values were translated into the number of deer–, elk–, or moose–vehicle collisions that need to occur per kilometer per year for a mitigation measure to start generating economic benefits in excess of costs. In addition, we calculated the costs associated with large ungulate–vehicle collisions on 10 road sections throughout the United States and Canada and compared these to the threshold values. Finally, we conducted a more detailed cost analysis for one of these road sections to illustrate that even though the average costs for large ungulate–vehicle collisions per kilometer per year may not meet the thresholds of many of the mitigation measures, specific locations on a road section can still exceed thresholds. We believe the cost–benefit model presented in this paper can be a valuable decision support tool for determining mitigation measures to reduce ungulate–vehicle collisions.

Key Words: animal–vehicle collisions; cost–benefit analysis; deer; economic; effectiveness; elk; human injuries and fatalities; mitigation measures; moose; roadkill; ungulate; vehicle repair cost; wildlife–vehicle collision

INTRODUCTION

Wildlife–vehicle collisions affect human safety, property, and wildlife. The total number of large mammal–vehicle collisions has been estimated at one to two million in the United States and at 43,000 in Canada annually (Conover et al. 1995, Tardif and Associates Inc. 2003, Huijser et al. 2007b). These numbers have increased even further over the last decade (Tardif and Associates Inc. 2008, Huijser et al. 2007b). In the United States, these collisions were estimated to cause 211 human fatalities, 39,000 human injuries and over one billion US dollars in property damage annually (Conover et al. 1995). In most cases, the animals die immediately or shortly after the collision (Allen and McCullough 1976). In some cases, it is not just the individual animals that suffer. Road mortality may also affect some species on the population level (e.g., van der Wal, Huijser, and Bergers 2000), and some species may even be faced with a serious reduction in population survival probability as a result of road mortality, habitat fragmentation, and other negative effects associated with roads and traffic (Brooker 2003, Huijser et al. 2007b). In addition, some species also represent a monetary value that is lost once an individual animal dies (Rosen et al. 1996, Conover 1997).

Cost-Benefit Model

• Collisions with large mammals are dangerous for people and expensive

• Mitigation measures are good for human safety and conservation, and can help society safe money
US93 N Costs and Benefits

Input:
• Evaro, Ravalli Curves and Ravalli Hill 76% reduction
• Shorter road sections 50% reduction
• Specific costs for the mitigation measures US93

Notes:
• Model is primary based on human safety
• Mitigation US93 N was primarily conducted because CSKT required it to protect cultural and natural resources
## US93 N Costs and Benefits

</tbody>
</table>
US93 N Costs and Benefits

Why negative balance?
• Fences are relatively inexpensive
• Crossing structures are relatively expensive

• US93 N has relatively high concentration of crossing structures
• US 93 N has predominantly short fences which are less effective in reducing collisions
• US 93 N has predominantly no fences or short fences at isolated structures (high costs per mitigated mi)

“Mitigation measures US93 N are predominantly a success”
General recommendations

- Select fence and crossing locations carefully (human safety – habitat connectivity)
- Make stream crossings suitable for terrestrial mammals, but don’t forget higher and drier areas.
- Formulate objectives related to habitat connectivity and design accordingly (e.g. target species, population viability).
- Combine crossing structures with wildlife fences.
- Fenced road length >5 km (consider home range).
- Fences should cover hotspot and buffer zone
- Include fence end treatments
- Increase spatial accuracy collision data
Recommendations US93 N

• Fence maintenance program
• Tie short fenced sections together
• Implement effective fence end treatments (electric mats)
• Electric mats in bear areas (gaps and fence ends)
• Make concrete ledges wildlife guards inaccessible
• Remove human access point
• Retrofit connections wing walls structures – fences
• Vegetation maintenance wildlife jump-outs
• Investigate improvements to wildlife guards (broken legs ungulates) electric mats (grizzly bears), and wildlife jump-outs (lower, be careful!)
